(54) Methods of manufacturing metal titanate fine powders.

(5) A method of manufacturing metal titanate fine powder which is represented as MTiO₃ where M is Ba, Sr or Ca includes the steps of preparing a hydrolised product of a titanium compound and reacting the hydrolised product with a water soluble metal salt of Ba, Sr or Ca in an aqueous alkaline solution having a pH of not less than 13.

METHODS OF MANUFACTURING METAL TITANATE FINE POWDERS

This invention relates to methods of manufacturing metal titenate fine powders, and more particularly is directed to methods of manufacturing barium titenate, strontium titenate and calcium titenate fine powder by liquid-phase reaction. The invention also relates to metal titenate fine powders made by such methods.

5

10

15

20

25

Recently, manufacture of metal titanate ultra-fine powder such as barium titanate BaTiO₃, strontium titanate SrTiO₃ and calcium titanate CaTiO₃ ultra-fine powders has been required for several uses. One such requirement relates to a multilayer ceramic capacitor, which is required to be small and light, like other electronic parts, but of large capacitance. In a multilayer ceramic capacitor, barium titanate, strontium titanate or calcium titanate are employed as a ferroelectric material. In order to make the thickness of the multilayer ceramic capacitor small and uniform, it is necessary to make the above material as ultra-fine powders. In addition, in such a multilayer ceramic capacitor, lead is mixed into the material because of its firing properties and temperature characteristics. However, if the firing temperature is high, the lead is partly evaporated, so that multilayer ceramic capacitors of uniform characteristics cannot be obtained. If an ultra-fine powder of a metal titanate such as barium titanate could be made finer, the firing temperature could be lower with improved results.

Moreover, metal titanate ultra-fine powders such as $BaTiO_3$, $SrTiO_3$ and $CaTiO_3$ ultra-fine powders are required for use as electrostrictive materials, piezo-electric materials as transparent ceramics.

BaTiO₃, SrTiO₃ and CaTiO₃ have been manufactured by calcination. More particularly, barium carbonate BaCO₃ powder and titanium oxide powder are mixed and calcined at 1000 to 1200°C; or strontium carbonate SrCO₃ powder and titanium oxide powder are mixed and calcined at 1000 to 1300°C; or calcium cabonate CaCO₃ powder and titanium oxide powder are mixed and calcined at 1000 to 1200°C. The calcined material thus made is mechanically ground to a fine powder, but the particle size is relatively large and not uniform, so to obtain fine and uniform particles, it is necessary to sieve the ground powder to eliminate large particles.

Moreover, it is difficult to avoid the introduction of impurities during these processes.

Recently it has also been proposed to synthesize metal titanate fine powders such as BaTiO₃, SrTiO₃ and CaTiO₃ using a metal alkoxide. However, this involves high manufacturing cost and therefore has not been used in practice. The size of BaTiO₃ particles obtained by this method is 500 angstroms.

5

10

15

20

25

30

35

The crystal system of the $BaTiO_3$ obtained with the above two methods is tetragonal (a_n =3.994 angstroms and c_n =4.038 angstroms).

According to the present invention there is provided a method of manufacturing metal titanate fine powder which is represented as MTiO₃ where M is Ba, Sr or Ca, comprising the steps of: preparing a hydrolysed product of a titanium compound; and reacting said hydrolysed product with a water soluble metal salt of Ba, Sr or Ca in an aqueous alkaline solution having a pH of not less than 13.

According to the present invention there is also provided a method of manufacturing barium titanate fine powder comprising the steps of: preparing a hydrolysed product of a barium compound; and reacting said hydrolysed product in an aqueous alkaline solution having a pH of not less than 13.

According to the present invention there is also provided a method of manufacturing strontium titenate fine powder comprising the steps of: preparing a hydrolysed product of a strontium compound; and reacting said hydrolysed product in an aqueous alkaline solution having a pH of not less than 13.

According to the present invention there is also provided a method of manufacturing calcium titanate fine powder comprising the steps of: preparing a hydrolysed product of a calcium compound; and reacting said hydrolysed product in an aqueous alkaline solution having a pH of not less than 13.

The invention will now be described by way of example with reference to the accompanying drawings, throughout which like parts are referred to by like references, and in which:

In methods according to the invention of manufacturing metal titenate MTiO₃ (where M is barium Ba, strontium Sr or calcium Ca) fine powder, a hydrolysation product of titenium Ti compound and a water soluble metal salt are reacted in a strong alkaline aqueous solution or suspension.

The methods wil first be described in detail in connection with the

manufacture of barium titanate BaTiO_3 fine powder. The Ti compound is prepared first. The titanium compound can, for example, be titanium tetrachloride TiCl_4 , titanyl sulphate $\operatorname{Ti(SO}_4)_2$ or titanoxy sulphate TiOSO_4 . This Ti compound is hydrolysed. For example, with TiCl_4 and $\operatorname{Ti(SO}_4)_2$ aqueous solutions thereof are made neutral thereby to obtain TiO_2 .xH $_2$ O. When $\operatorname{Ti(SO}_4)_2$ is employed, in order to remove the sulphate group, rinsing by water is performed to filter TiO_2 .xH $_2$ O.

5

10

15

20

25

30

35

Next, a water soluble barium salt is prepared and then reacted with the above hydrolysed product in suspension in the strong alkaline aqueous solution. When in the hydrolysation reaction, filtering to remove the sulphate group or the like is not required, the reaction in the suspension of strong alkaline aqueous solution can be carried out at the same time as the hydrolysation reaction.

The water soluble Ba salt can be $Ba(NO_3)_2$, $Ba(OH)_2$, $BaCl_2$ or $Ba(CH_3COO)_2$, while the alkali can be LiOH, KOH, NaOH or $NH_\Delta OH$.

The pH of the suspension of strong alkaline equeous solution is selected to be higher than 13.0, more preferably 13.5 or above. The molar ratio between Ba and Ti, Ba/Ti, is selected to be more than 0.5, more preferably 0.7 to 5. The reaction temperature is selected to be higher than 15° C, possibly up to the boiling point of the aqueous solution, and preferably higher than 40° C. The reaction time is selected to be sufficient to effect the reaction.

After the reactions as described above, filtering, rinsing and drying treatments are carried out, if necessary.

With this method of manufacture, BaTiO₃ fine powder having a uniform particle size as small as 200 to 300 angstroms can be obtained. Since in the previously proposed synthesis based upon calcination, the BaTiO₃ was mechanically ground to a fine powder, the above particle size of 200 to 300 angstroms could not be expected. When the BaTiO₃ fine powder made by a method according to the invention is used for forming a multilayer ceramic capacitor, the firing temperature can be lowered. Thus lead can be mixed uniformly into the BaTiO₃ fine powder, removing the scatter characteristics. Then, since the dielectric constant of the material can be increased at room temperature, it is possible to achieve a large capacitance for the capacitor. The BaTiO₃ fine powder thus made is also very suitable as electrostrictive material, piezoelectric material and

transparent ceramics.

5

10

15

25

Moreover, since inorganic material is used as the raw material, the manufacturing cost can be lowered significantly.

Also, the absence of the grinding process means that impurities are not mixed into the BaTiO, fine powder.

Using methods according to the invention, cubic system BaTiO $_3$ (a $_0$ =4.033 angstroms) can be obtained.

The manufacture of strontium titanate SrTiO₃ fine powder will now be described. In the same way as with barium titanate fine powder, a hydrolysed product of Ti compound is prepared. Then, a water soluble Sr salt is prepared and is reacted with the above hydrolysed product of the Ti compound in a strong alkaline aqueous solution. When in the hydrolysed reaction, filtering to remove the sulphate group or the like is not required, the reaction in the strong alkaline aqueous solution can be carried out at the same time as the hydrolysation reaction.

The water soluble Sr salt can be $Sr(NO_3)_2$, $Sr(OH)_2$, $SrCl_2$, $Sr(CH_3COO)_2$ or SrO, while the alkali can be LiOH, KOH, NaOH or NH₄OH.

The pH of the strong alkali aqueous solution is selected to be higher than 13.0. The molar ratio between Sr and Ti, Sr/Ti, is selected to be more than 0.3, more preferably 0.5 to 4. The reaction temperature is selected to be higher than 20°C, possibly up to the boiling point of the aqueous solution, and preferably higher than 60°C. The reaction time is selected to be sufficient to effect the reaction.

After the reactions as described above, filtering, rinsing and drying treatments are carried out, if necessary.

With this method of manufacture, SrTiO₃ fine powder having a uniform particle size as small as 100 to 200 angstroms can be obtained. Since in the previously proposed synthesis based on calcination, the SrTiO₃ was mechanically ground to a fine powder, the above particle size of 100 to 200 angstroms could not be expected. When the SrTiO₃ fine powder made by a method according to the invention is used for forming a multilayer ceramic capacitor, the firing temperature can be lowered. Thus, lead can be mixed uniformly into the SrTiO₃ fine powder, removing the scatter characteristics. Then, since the dielectric constant of the material can be increased at room temperature, it is possible to achieve a large capacitance for the capacitor. The SrTiO₃ fine powder thus made is also very suitable as

electrostrictive material, piezoelectric material and transparent ceramics.

Moreover, since inorganic material is used as the raw material, the manufacturing cost can be lowered significantly.

Moreover, the absence of the grinding process means that impurities are not mixed into the ${\rm SrTiO_3}$ fine powder.

5

10

15

20

25

Using methods according to the invention, cubic system $SrTiO_3$ (a₀=3.921 angstroms) can be obtained.

Also, when CaTiO₃ fine powder is to be manufactured, a hydrolysed product of titanium Ti compound is prepared similarly. Then, a water soluble Ca salt is prepared and reacted with the above hydrolysed product of Ti compound in the suspension of strong alkaline aqueous solution. When in the hydrolysed reaction, filtering to remove the sulphate group or the like is not necessary, the reaction in the strong alkaline aqueous solution can be carried out at the same time as the above hydrolysation reaction.

The water soluble Ca salt can be ${\rm Ca(NO_3)_2}$, ${\rm Ca(OH)_2}$, ${\rm CaCl_2}$, ${\rm Ca(CH_3COO)_2}$ or CaO, while the alkali can be LiOH, KOH, NaOH or NH₄OH.

The pH of the suspension of strong alkaline aqueous solution is selected to be higher than 13.0, more preferably higher than 13.2. The molar ratio between Ca and Ti, Ca/Ti, is selected to be more than 0.3, more preferably 0.6 to 10. The reaction temperature is selected to be higher than 70°C, possibly up to the boiling point of the aqueous solution, and preferably higher than 85°C. The reaction time is selected to be sufficient to effect the reaction.

After the reactions as described above, filtering, rinsing and drying treatments are carried out, if necessary.

With this method of manufacture, CaTiO₃ uniform fine powder having a particle size as small as 1 to 3 microns can be obtained. Since in the previously proposed synthesis based on calcination, the CaTiO₃ was mechanically ground to a fine powder, the above particle size of 1 to 3 microns could not be expected. When the CaTiO₃ fine powder made by a method according to the invention is used for forming a multilayer ceramic capacitor, the firing temperature can be lowered. Thus, lead can be mixed uniformly into the CaTiO₃ fine powder, removing the scatter characteristics. Then, since the dielectric constant of the material can be increased at room temperature, it is possible to achieve a large capacitance

for the capacitor. The CaTiO₃ fine powder thus made is also very suitable as electrostrictive material, piezoeletric material and transparent ceramics.

Moreover, since inorganic material is used as the raw material, the manufacturing cost can be lowered significantly.

Moreover, the absence of the grinding process means that impurities are not mixed into the $CaTiO_3$ fine powder.

Using methods according to the invention, rhombic system ${\tt CaTiO_3}$ fine powder can be obtained.

The invention will now be described in more detail with reference to examples.

Example 1

5

10

15

20

25

30

35

 $50~{\rm g}$ of TiCl₄ was added to and stirred into $50~{\rm ml}$ of water to make an aqueous solution to which aqueous solution including Ba(NO₃)₂ of molar amount equivalent to the Ti was added. KOH was further added thereto to make the pH 13.5. Then, while stirring the aqueous solution, the aqueous solution was continuously reacted at the reaction temperature of $100^{\circ}{\rm C}$ for four hours. The product made by this reaction was filtered, and the product rinsed with water and dried at $70^{\circ}{\rm C}$ for one day.

As a result of X-ray analysis of the product thus made, the diffraction pattern as shown in Figure 1 was obtained. Comparing this diffraction pattern with an American Society of Testing Materials (ASTM) card, it was confirmed that the BaTiO₃ thus made was of cubic system. In this case, the X-ray diffraction was performed by the powder method in which a copper target and nickel filter were used, and the time constant was selected to be "1". Moreover, as will be clear from a dark image and a bright image obtained by an electron microscope and as shown in Figures 2 and 3, the particle size of the BaTiO₃ fine powder in this example was in a range from 200 to 300 angstroms and uniform.

Example 2

50 g of TiCl₄ was added to and stirred into 100 g of water to make an aqueous solution to which NH₄OH was added and hydrolysed to form a substantially neutral aqueous solution. Thereafter, Ba(OH)₂ in a molar amount of 0.95, approximately the same as the Ti, was added to the above neutral aqueous solution to which KOH was added to make the pH 14. The aqueous solution was then reacted at the reaction temperature of 90°C for three hours, then filtered, and the product rinsed with water and dried at

100°C for one day. The product was subjected to the same X-ray analysis as described above, resulting in a diffraction pattern similar to Figure 1. Also, the results with an electron microscope were the same as those of Figures 2 and 3.

Furthermore, the $BaTiO_3$ fine powder of this example was subjected to differential thermal analysis and thermogravimetric analysis. The results thereof are indicated in Figures 4 and 5, respectively. As will be understood from these results, the $BaTiO_3$ fine powder contains no impurity. The dropped portion on the curve shown by a reference letter \underline{a} in Figure 4 is believed to be caused by the dehydration of the absorption water.

Example 3

5

15

20

25

30

50 g of TiCl₄ was added to and stirred into 200 g of water to make an aqueous solution to which NaOH was added to make the aqueous solution substantially neutral. Thereafter, BaO was added to the neutral aqueous solution to which NaOH was further added to make the pH 13.7. This aqueous solution was reacted at 95°C for two hours, filtered, and the product rinsed with water and then dried at 100°C for one day. The product was subjected to the same X-ray analysis as described above, resulting in a diffraction pattern similar to Figure 1. Also, the results with an electron microscope were the same as those of Figures 2 and 3.

Example 4

50 g of TiCl₄ was added to and stirred into water to make an aqueous solution to which KOH was added to make the aqueous solution substantially neutral. Then, Ba in a molar amount twice that of the Ti was added to the above neutral aqueous solution to which KOH was further added to make the pH 13.3. In this state, this aqueous solution was reaction at 95°C for two hours. Thereafter, a top clear part of the solution was removed by decanting and water was added thereto again. This treatment was repeated and the product was rinsed with water. The product thus made then had an aqueous solution of NH₄Cl added, was filtered, rinsed with water and then dried at 100°C for one day. This product was subjected to the same X-ray analysis as described above, resulting in a diffraction pattern similar to Figure 1. Also, the results with an electron microscope were the same as those of Figures 2 and 3.

35 Example 5

In this example, the pH dependency of the synthesised amount of

BaTiO₃ was examined. Ba solution (suspension solution) of a molar amount equivalent to the Ti was added to the hydrolysed product of TiCl₄ to which KOH was then added. Then, the amount of BaTiO₃ synthesized when the solution thus made was reacted at 100°C for four hours was measured. The amount of BaTiO₃ synthesized was measured each time the amount of KOH added was varied to change the pH. The measured results are shown in the graph of Figure 6, which shows that the pH should be selected to be higher than 13.0, preferably higher than 13.5. In this case, the amount of BaTiO₃ produced was calculated from the area of the X-ray diffraction peak (110) of cubic-system perovskite. The X-ray analysis was carried out in substantially the same way as described above. That is, a copper target and a cobalt filter were employed, a voltage of 35 kV and a current of 25 mA were applied and the time constant was selected to be "1".

Example 6

5

10

15

20

25

30

35

In this example, the relation between the synthesized amount of $BaTiO_3$ and the molar ratio was studied. $Ba(OH)_2$ of a predetermined amount was added to the hydrolysed product of $TiCl_4$ to which KOH was added to make the pH 14.0. The solution thus made was reacted at $100^{\circ}C$ for four hours and thereafter, the amount of $BaTiO_3$ synthesized was measured. While changing the amount of $Ba(OH)_2$, dependency of the amount of $BaTiO_3$ synthesized on the molar ratio Ba/Ti was studied. The results are shown in the graph of Figure 7, which shows that the molar ratio Ba/Ti should be higher than 0.5, preferably in a range from 0.7 to 5. In this case, the amount of $BaTiO_3$ synthesized was measured in the same way as in Example 5.

Example 7

In this example, the temperature dependency of the amount of BaTiO₃ synthesized was studied. Ba solution of the same molar amount as the Ti was added to the hydrolysed product of TiCl₄ to which KOH was then added to make the pH 13.9. The aqueous solution thus made was reacted for three hours. Then, the amount of BaTiO₃ synthesized was measured for reaction temperatures over a range from 15°C to the boiling point of the aqueous solution. The measured results are shown in the graph of Figure 8, which shows that the reaction temperature should be in a range from 15°C to the boiling point, preferably higher than 40°C. In this case, the amount of BaTiO₃ synthesized was measured in the same way as in Example 5.

Example 8

5

10

15

20

25

30

35

In this example, the time dependency of the amount of BaTiO₃ synthesized was studied. Ba solution of the same molar amount as the Ti was added to the hydrolysed product of TiCl₄ to which KOH was then added to make the pH 13.9. The aqueous solution thus made was reacted at 50°C, 70°C and 90°C, respectively. Then, the amount of BaTiO₃ synthesized was measured for every reaction time. The results are shown in the graph of Figure 9. A sufficient time for enabling the reaction to be achieved can be measured from the graph of Figure 9. Also, in this example, the amount of BaTiO₃ synthesized was measured in the same way as in Example 5.

Example 9

50 g of $TiCl_4$ was added to and stirred into 50 ml of iced water to make an aqueous solution to which a $Sr(NO_3)_2$ aqueous solution of molar amount equivalent to the Ti was added. KOH was further added to the solution to make the pH 13.7. Thereafter, the aqueous solution thus made was continuously reacted at $100^{\circ}C$ for four hours. The product of this reaction was filtered, rinsed with water and then dried at $70^{\circ}C$ for one day. This product was subjected to X-ray analysis, resulting in the diffraction pattern as shown in Figure 10. Comparing this diffraction pattern with an ASTM card, it was confirmed that the $SrTiO_3$ obtained was a cubic-system $SrTiO_3$ (a₀ = 3.921 angstroms) fine powder. X-ray analysis was carried out by the powder method in which a copper target and a nickel filter were used. As will be clear from a dark image and a bright image shown in Figures 11 and 12, and obtained with an electron microscope, the particle size of the $SrTiO_3$ fine powder was in a range from 100 to 200 angstroms and uniform.

Example 10

50 g of TiCl₄ was added to and stirred into 100 g of water to make an aqueous solution to which NH₄OH was added to be hydrolised, and form a neutral aqueous solution of pH 7. Thereafter, Sr(OH)₂ in a molar amount approximately the same as the Ti (Sr/Ti = 1.05) was added to the neutral aqueous solution to make the pH 14. The aqueous solution thus made was reacted at 95°C for four hours. Then, the product was filtered, rinsed with water and then dried at 100°C for one day. This product was subjected to similar X-ray analysis, resulting in the same diffraction pattern as in Figure 10. Moreover, the results obtained with an electron microscope were the same as those in Figures 11 and 12.

Example 11

5

10

15

20

25

30

35

50 g of TiCl₄ was added to and stirred into 200 g of water to make an aqueous solution of Ti to which NaOH was added to make a neutral solution of pH 7. SrCl₂ of the same molar amount as the Ti was added to the solution to which NaOH was further added to make the pH 14. The resulting solution was reacted at 100°C for three hours. The product thus made was filtered, rinsed with water and then dried at 100°C for one day. The product was subjected to the same X-ray analysis as mentioned above, resulting in a diffraction pattern the same as that shown in Figure 10. Moreover, results with an electron microscope were similar to those shown in Figures 11 and 12.

Example 12

NH₄OH was added to 200 ml of a 30 weight % of Ti(SO₄)₂ aqueous solution to make a neutral aqueous solution of pH 7, which was then filtered and the product rinsed with water. Thereafter, the product had added 11 of water to which SrCl₂ in a molar amount equal to the Ti was added. KOH was also added thereto to make the pH 14, and the resulting solution was reacted at 100°C for four hours. The product thus made was filtered, rinsed with water and then dried. This product was subjected to the same X-ray analysis as mentioned above, resulting in a diffraction pattern the same as that shown in Figure 10. Moreover, the results with an electron microscope were similar to those shown in Figures 11 and 12.

Example 13

In this example, the pH dependency of the amount of the SrTiO₃ synthesized was measured. TiCl₄ was hydrolysed, and Sr salt in the same molar amount as the Ti and then KOH were added. Then, the amount of SrTiO₃ synthesized when the aqueous solution thus made was reacted at 100°C for three hours was measured. In this case, the amount of KOH added was varied so as to change the pH of the above aqueous solution. The results thereof are shown in the graph of Figure 13, which shows that the pH should be selected to be higher than 13.0. In this case, the amount of SrTiO₃ synthesized was measured from the area of the X-ray diffraction peak (110).

Example 14

In this example, the dependency of the amount of the SrTiO₃ synthesized upon the molar ratio was studied. In this example, the SrTiO₃

was made in the same way as Example 13 where the pH was 14. Then, the molar ratio Sr/Ti was changed. The results thereof are shown in the graph of Figure 14, which shows that the molar ratio should be higher than 0.3, preferably in a range from 0.5 to 4. In this case, the amount of SrTiO₃ synthesized was measured in the same way as in Example 13.

Example 15

5

10

15

20

25

30

35

In this example, the temperature dependency of the amount of SrTiO₃ synthesized was studied. In this example also, the SrTiO₃ was made in the same way as in Example 13 where the molar ratio of Sr/Ti was 1.05 and the pH was 14. Then, the reaction temperature was changed. The results are shown in the graph of Figure 15, which shows that the reaction temperature is preferably selected in a range from 20°C to the boiling point of the aqueous solution, more preferably higher than 60°C. In this case, the amount of SrTiO₃ synthesized was measured in the same way as in Example 13.

Example 16

In this example, the dependency on time of the amount of SrTiO₃ synthesized was studied. Also in this example, the SrTiO₃ was made in the same way as in Example 13 where the pH was 14 and the molar ratio Sr/Ti was 1.05. Then, the reaction time was changed. The results are shown in the graph of Figure 16. From this graph, it is seen how the time affects the amount SrTiO₃ synthesized, the amount being measured in the same way as in Example 13.

Example 17

In this example, differential thermal analysis and thermogravimetric analysis were carried out. Also in this example, the ${\rm SrTiO}_3$ was made in the same way as in Example 13 with the pH 14. In the analysis, the temperature was raised at a rate of $20^{\rm O}{\rm C/min}$. The results thereof are shown in the graphs of Figures 17 and 18, respectively. These graphs indicate that the ${\rm SrTiO}_3$ fine powder contains no impurity. In this case, the dropped portion indicated by a reference letter <u>a</u> in Figure 17 is believed to be caused by the dehydration of the adsorption water.

Example 18

50 g of ${\rm TiCl_4}$ was added to and stirred into 50 ml of iced water to make an aqueous solution to which ${\rm Ca(NO_3)_2}$ aqueous solution of the same molar amount as the Ti was added. KOH was then added, thereby making

the pH of this aqueous solution 13.7. Thereafter, while being stirred, this aqueous solution was continuously reacted at 100°C for four hours. The product made by this reaction was filtered, rinsed with water and then dried at 70°C for one day. This product was subjected to X-ray analysis, resulting in a diffraction pattern shown in Figure 19. The comparison of this diffraction pattern with the ASTM card confirmed the fact that the CaTiO₃ thus made was a rhombic-system CaTiO₃. The X-ray analysis was performed using the powder method with a copper target and a nickel filter. Moreover, as will be clear from a photograph obtained with a scanning electromicroscope and shown in Figure 20, the particle size of the CaTiO₃ fine powder in this example was in a range from 1 to 3 microns and uniform.

35

50 g of TiCl₄ was added to and stirred into 100 g of water to make an aqueous solution to which NH₄OH was added so as to make the solution substantially neutral. Then, Ca(OH)₂ in a molar amount substantially equal to the Ti was added to the above aqueous solution, to which KOH was further added to make the pH 14. This aqueous solution was reacted at 95°C for four hours. Thereafter, the product thus made was filtered, rinsed with water and then dried at 100°C for one day. The product was subjected to the same X-ray analysis as described above, resulting in a diffraction pattern similar to that of Figure 19. Also, the result obtained with a scanning electromicroscope was the same as that shown in Figure 20.

Example 20

50 g of TiCl₄ was added to and stirred into 200 g of water to make an aqueous solution to which NaOH was added to make the aqueous solution substantially neutral, that is, pH 7. Then, CaCl₂ in a molar amount equal to the Ti was added to the aqueous solution, to which NaOH was further added to make the pH 14. This aqueous solution was reacted at 100°C for three hours. Thereafter, the product thus made was filtered, rinsed with water and then dried at 100°C for one day. This product was subjected to the same X-ray analysis as described above, resulting in a diffraction pattern similar to that of Figure 19. Also, the result obtained with a scanning electromicrosope was the same as that shown in Figure 20.

Moreover, the CaTiO₃ fine powder of this example was subjected to differential thermal analysis and thermogravimetric analysis in which the temperature was raised at a rate of 20°C per minute. The results thereof

are shown in the graphs of Figures 21 and 22, respectively, which show that the CaTiO₃ fine powder contains no impurity. In this case, the dropped portion indicated by a reference letter <u>a</u> in Figure 21 is believed to be caused by the dehydration of the adsorption water.

Example 21

35

NH₄OH was added to 200 ml of 30 weight % Ti(SO₄)₂ aqueous solution to make a substantially neutral aqueous solution of pH 7, which was then filtered and the product rinsed with water. Thereafter, this product was added to 1 l of water to which CaCl₂ in a molar amount equal to the Ti was added. KOH was added thereto make the pH 14, and then the aqueous solution was continuously reacted at 100°C for four hours. Thereafter, the product thus made was filtered out, rinsed with water and then dried. This product was subjected to the same X-ray analysis as described above, resulting in a diffraction pattern similar to that of Figure 19. Also, the result obtained with a scanning electromicroscope was the same as that shown in Figure 20.

Example 22

In this example, the pH dependency of the amount of CaTiO₃ synthesized was studied. A Ca salt in a molar amount equal to the Ti was added to a hydrolyzed product of TiCl₄ to which KOH was added thereafter. Then, the amount of CaTiO₃ synthesized when this equeous solution was reacted at 100°C for three hours was measured. Then, the amount of CaTiO₃ synthesized was measured with the amount of KOH added varied to change the pH. The results are shown in the graph of Figure 23, which shows that the pH should be selected to be higher than 13.0, preferably higher than 13.2. In this case, the amount of CaTiO₃ synthesized was measured from the areas of the X-ray diffraction peaks (200) and (121) of the rhombic-system CaTiO₃. The X-ray analysis was carried out in substantially the same way as described above.

Example 23

In this example, the dependency of the amount of $CaTiO_3$ synthesized on the molar ratio was measured. $Ca(OH)_2$ of a predetermined amount was added to the hydrolysed product of $TiCl_4$ to which KOH was then added to make the pH 14.0. Then, this aqueous solution was reacted at $100^{\circ}C$ for three hours. Thereafter, the amount of $CaTiO_3$ synthesized was measured. And, while changing the amount of $Ca(OH)_2$, thus changing the molar ratio

Cr/Ti, the amount of CaTiO₃ synthesized was measured. The results are shown in the graph of Figure 24 which shows that the molar ratio Ca/Ti should be selected to be higher than 0.3, preferably in a range from 0.6 to 10. In this case, the amount of CaTiO₃ synthesized was measured in the same way as in Example 22.

Example 24

5

10

15

20

25

In this example, the temperature dependency of the amount of CaTiO₃ synthesized was studied. Ca solution in a molar amount of 1.05 approximately equal to the Ti was added to the hydrolysed product of TiCl₄, to which KOH was added then to make the pH 14, and the aqueous solution was then reacted for three hours. Then, the amount of CaTiO₃ synthesized was measured at each reaction temperature. The results are shown in the graph of Figure 25, which shows that the reaction temperature should be selected in a range from 70°C to the boiling point of the aqueous solution, more preferably higher than 85°C. In this case, the amount of CaTiO₃ synthesized was measured in the same way as in Example 22.

Example 25

In this example, the time dependency of the amount of CaTiO₃ synthesized was studied. Ca solution of a molar amount 1.05 approximately equal to the Ti was added to the hydrolysed product of TiCl₄, to which KOH was added to make the pH 14, and the resulting aqueous solution then was reacted at 100°c. The amount of CaTiO₃ synthesized was measured at each reaction time. The results are shown in the graph of Figure 26, from which the time dependency is seen. Also, in this example, the amount of CaTiO₃ synthesized was measured in the same way as in Example 22.

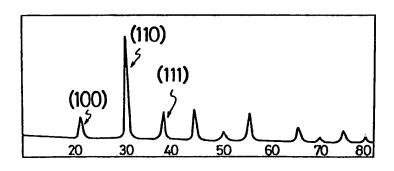

CLAIMS

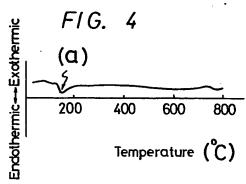

- 1. A method of manufacturing metal titenate fine powder which is represented as MTiO₃ where M is Ba, Sr or Ca, comprising the steps of: preparing a hydrolysed product of a titenium compound; and reacting said hydrolysed product with a water soluble metal sait of Ba, Sr or Ca in an aqueous alkaline solution having a pH of not less than 13.
- 2. A method of manufacturing barium titanate fine powder comprising the steps of: preparing a hydrolysed product of a barium compound; and reacting said hydrolysed product in an aqueous alkaline solution having a pH of not less than 13.
- 3. A method of manufacturing strontium titanate fine powder comprising the steps of: preparing a hydrolysed product of a strontium compound; and reacting said hydrolysed product in an aqueous alkaline solution having a pH of not less than 13.
- 4. A method of manufacturing calcium titanate fine powder comprising the steps of: preparing a hydrolysed product of a calcium compound; and reacting said hydrolysed product in an aqueous alkaline solution having a pH of not less than 13.
- 5. A method of manufacturing barium titanate fine powder and according to claim 2 wherein said aqueous alkaline solution has a pH of not less than 13.5.
- 6. A method of manufacturing barium titenate fine powder and according to claim 2 wherein the molar ratio Ba/Ti is not less than 0.5.
- 7. A method of manufacturing barium titenate fine powder and according to claim 2 wherein the molar ratio Ba/Ti is in a range from 0.7 to 5.

- 8. A method of manufacturing barium titenate fine powder and according to claim 2 wherein the reaction temperature is not less than 15°C .
- 9. A method of manufacturing barium titanate fine powder and according to claim 2 wherein a reaction temperature is in a range from 40° C to the boiling point of said aqueous solution.
- 10. A method of manufacturing strontium titanate fine powder and according to claim 3 wherein the molar ratio Sr/Ti is not less than 0.3.
- 11. A method of manufacturing strontium titenate fine powder and according to claim 3 wherein the molar ratio Sr/Ti is in a range from 0.5 to 4.
- 12. A method of manufacturing strontium titanate fine powder and according to claim 3 wherein the reaction temperature is not less than 20°C .
- 13. A method of manufacturing strontium titanate fine powder and according to claim 3 wherein the reaction temperature is in a range from 60° C to the boiling point of said aqueous solution.
- 14. A method of manufacturing calcium titenate fine powder and according to claim 4 wherein said aqueous alkaline solution has a pH of not less than 13.2.
- 15. A method of manufacturing calcium titenate fine powder and according to claim 4 wherein the molar ratio Ca/Ti is not less than 0.3.
- 16. A method of manufacturing calcium titenate fine powder and according to claim 4 wherein the molar ratio Ca/Ti is in a range from 0.6 to 10.
- 17. A method of manufacturing calcium titanate fine powder and according to claim 4 wherein the reaction temperature is not less than 70° C.

- 18. A method of manufacturing calcium titanate fine powder and according to claim 4, wherein the reaction temperature is in a range from 25°C to the boiling point of said aqueous solution.
- 19. A method of manufacturing metal titanate fine powder and according to any one of claims 1 to 4 wherein said titanium compound is ${\rm TiCl}_4$, ${\rm TiOSO}_4$ or ${\rm Ti(SO}_4)_2$.
- 20. A method of manufacturing barium titanate fine powder and according to claim 2 wherein said barium compound is $Ba(NO_3)_2$, $Ba(OH)_2$, $BaCl_2$ or $Ba(CH_3COO)_2$.
- 21. A method of manufacturing strontium titanate fine powder and according to claim 3 wherein said strontium compound is $Sr(NO_3)_2$, $Sr(OH)_2$, $Sr(CH_3COO)_2$ or SrO.
- 22. A method of manufacturing calcium titanate fine powder and according to claim 4 wherein said calcium compound is $Ca(NO_3)_2$, $Ca(OH)_2$, $Ca(CH_3COO)_2$ or CaO.
- 23. Barium titanate fine powder, strontium titanate fine powder or calcium titanate fine powder made by a method according to any one of the preceding claims.
